What are the important considerations in choosing this test?

* It is possible that a diagnosis unrelated to the reason of testing may be found including predisposition to mental retardation, autism, cancer, late-onset disease or other medical conditions.
* There is a small chance of finding a genetic condition affecting the health of yourself or other family members.
* The test result may still be uncertain even after parental blood is tested.
* The above may impose psychological distress.
* You need to indicate what information you would like to know from the test.

What are the limitations of this test?

* aCGH test does not look at the structural arrangement of chromosomes (these are supplemented by conventional chromosome study by karyotyping).
* aCGH test does not look for individual gene changes.
* aCGH cannot detect low level mosaicism (presence of cells with different chromosomal makeup in an individual).
* A normal aCGH test result cannot exclude all abnormalities.

aCGH is a special test which finds differences in the amount of genetic material among individuals. It is more sensitive than traditional cytogenetic karyotyping and is able to find a chromosome gain or loss even if testing of the chromosome by karyotyping shows normal results.

These smaller imbalances, possible gains or losses of genetic material, are called ‘submicroscopic imbalances’ because they cannot be seen through the microscope. They may cause birth defects, delays in development, and genetic syndromes.

Whole genome aCGH is the recommended test for individuals with developmental or congenital problems. The clinical geneticist will assess if the test is necessary for your child.

The DNA of the patient is matched with a control DNA sample on the array to detect gain or loss of genetic material in the patient.

There are three possible test results:
1. **Normal** – no clinically significant gain or loss of genetic material is detected in the chromosome.
2. **Abnormal** – gain or loss of genetic material is detected in the chromosome. The clinical features associated with these results depend on the specific genetic material that is gained or lost.
3. **Unclear** – gain or loss of genetic material is detected in the chromosome but the effect is uncertain. Performing aCGH test on the blood samples taken from both biological parents may help in interpretation.
